

Introduction to Dempster-Shafer Theory of Belief Functions

David Mercier & Eric Lefevre

Université d'Artois

Tutorial PFIA 2022 - Lundi 27 juin 2022

Introduction

Dempster-Shafer (DS) theory of belief functions

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.

Introduction

Dempster-Shafer (DS) theory of belief functions

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.
- ▶ Also known as **Dempster-Shafer (DS) theory** or **Evidence theory** or **Belief Function Theory**.

Introduction

Dempster-Shafer (DS) theory of belief functions

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.
- ▶ Also known as **Dempster-Shafer (DS) theory** or **Evidence theory** or **Belief Function Theory**.
- ▶ It was introduced by **A. P. Dempster** in the 1960's for statistical inference, and developed by **G. Shafer** in the late 1970's into a general theory for reasoning under uncertainty.

Introduction

Dempster-Shafer (DS) theory of belief functions

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.
- ▶ Also known as **Dempster-Shafer (DS) theory** or **Evidence theory** or **Belief Function Theory**.
- ▶ It was introduced by **A. P. Dempster** in the 1960's for statistical inference, and developed by **G. Shafer** in the late 1970's into a general theory for reasoning under uncertainty.
- ▶ DS encompasses **probability theory** and **set-membership** approaches as special cases.

Introduction

Dempster-Shafer (DS) theory of belief functions

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.
- ▶ Also known as **Dempster-Shafer (DS) theory** or **Evidence theory** or **Belief Function Theory**.
- ▶ It was introduced by **A. P. Dempster** in the 1960's for statistical inference, and developed by **G. Shafer** in the late 1970's into a general theory for reasoning under uncertainty.
- ▶ DS encompasses **probability theory** and **set-membership** approaches as special cases.
- ▶ It is very general: many applications in AI (expert systems, machine learning), engineering (information fusion, uncertainty quantification, risk analysis), statistical inferences, etc.
- ▶ Evidential reasoning can be applied to **very large problems**.

► **Uncertainty**

Example: “I think John is 1.8m tall”

In this case, the piece of information “John is 1.8m tall” is precise but uncertain

► **Imprecision**

Example: “John is between 1.7m and 1.9m tall”

In this case, the piece of information “John is between 1.7m and 1.9m tall” is certain but imprecise

Introduction

Different types of imperfect information

▶ **Uncertainty**

Example: “I think John is 1.8m tall”

In this case, the piece of information “John is 1.8m tall” is precise but uncertain

▶ **Imprecision**

Example: “John is between 1.7m and 1.9m tall”

In this case, the piece of information “John is between 1.7m and 1.9m tall” is certain but imprecise

▶ **Imprecision and uncertainty**

Example: “I think John is between 1.7m and 1.9m tall”

In this case, the piece of information “John is between 1.7m and 1.9m tall” is both uncertain and imprecise

Introduction

Different types of imperfect information

- ▶ **Uncertainty** ⇒ Classically tackled with probabilities

Example: "I think John is 1.8m tall"

In this case, the piece of information "John is 1.8m tall" is precise but uncertain

- ▶ **Imprecision**

Example: "John is between 1.7m and 1.9m tall"

In this case, the piece of information "John is between 1.7m and 1.9m tall" is certain but imprecise

- ▶ **Imprecision and uncertainty**

Example: "I think John is between 1.7m and 1.9m tall"

In this case, the piece of information "John is between 1.7m and 1.9m tall" is both uncertain and imprecise

Introduction

Different types of imperfect information

- ▶ **Uncertainty** ⇒ Classically tackled with probabilities

Example: "I think John is 1.8m tall"

In this case, the piece of information "John is 1.8m tall" is precise but uncertain

- ▶ **Imprecision** ⇒ Classically tackled with sets

Example: "John is between 1.7m and 1.9m tall"

In this case, the piece of information "John is between 1.7m and 1.9m tall" is certain but imprecise

- ▶ **Imprecision and uncertainty**

Example: "I think John is between 1.7m and 1.9m tall"

In this case, the piece of information "John is between 1.7m and 1.9m tall" is both uncertain and imprecise

Aleatory uncertainty (Randomness)

VS

Epistemic uncertainty (Lack of knowledge)

Introduction

Difficulties to represent ignorance with probabilities

"Le tiercé c'est mon dada" (O. Sharif)

- ▶ Consider a **horse race** with three horses h_1 , h_2 and h_3

Expert 1: "All three horses have an equal chance of winning (same level)"

$$\text{Model: } p(\{h_1\}) = p(\{h_2\}) = p(\{h_3\}) = \frac{1}{3}$$

Expert 2: "I have no idea (complete ignorance)"

$$\text{Model: } p(\{h_1\}) = p(\{h_2\}) = p(\{h_3\}) = \frac{1}{3}$$

Le Derby d'Epsom (Géricault)

Introduction

Difficulties to represent ignorance with probabilities

"Le tiercé c'est mon dada" (O. Sharif)

- ▶ Consider a **horse race** with three horses h_1 , h_2 and h_3

Expert 1: "All three horses have an equal chance of winning (same level)"

$$\text{Model: } p(\{h_1\}) = p(\{h_2\}) = p(\{h_3\}) = \frac{1}{3}$$

Expert 2: "I have no idea (complete ignorance)"

$$\text{Model: } p(\{h_1\}) = p(\{h_2\}) = p(\{h_3\}) = \frac{1}{3}$$

Le Derby d'Epsom (Géricault)

- ▶ **Problem:** Two distinct pieces of information are modeled identically.
- ▶ There is a need for a richer model.

Representation of information

Combining information

Decision making

Conclusion

Representation of information

Combining information

Decision making

Conclusion

Representation of information

Mass functions — Definition

- ▶ Let us consider a variable of interest X taking its values into a finite set of hypotheses $\Omega = \{\omega_1, \dots, \omega_K\}$ called the universe or the **frame of discernment**.
 - ▶ **Example:** the horse that will win the race. $\Omega = \{h_1, h_2, h_3\}$
- ▶ A piece of information regarding the value ω_0 taken by this variable can be represented using a **mass function (MF)** m defined as a mapping $m : 2^\Omega \rightarrow [0, 1]$ verifying

$$\sum_{A \subseteq \Omega} m^\Omega(A) = 1 .$$

- ▶ The real $m(A)$ represents **the part of belief allocated to the hypothesis that the searched true value ω_0 belongs to A and nothing more.**
- ▶ A set A s.t. $m(A) > 0$ is called a **focal set** of m .

Representation of information

Mass functions — Example

“Si vous avez perdu au tiercé, vengez-vous. Mangez du cheval.” (P. Dac)

- ▶ Let us consider again the **horse race** example with $\Omega = \{h_1, h_2, h_3\}$

Expert 1: “All three horses have an equal chance of winning (same level)”

$$\text{Model: } m(\{h_1\}) = m(\{h_2\}) = m(\{h_3\}) = \frac{1}{3}$$

Expert 2: “I have no idea (complete ignorance)”

$$\text{Model: } m(\{h_1, h_2, h_3\}) = 1$$

Le Derby d'Epsom (Géricault)

Representation of information

Mass functions — Special cases

- ▶ If the evidence tells us that the truth is in $A \subseteq \Omega$ for sure, then we have a **logical** or **categorical mass function** m_A s.t. $m_A(A) = 1$.
- ▶ m_Ω represents the **total ignorance**, it is called the **vacuous mass function**
- ▶ If all focal sets of m are singletons, m is said to be **Bayesian**. It is equivalent to a probability distribution.
- ▶ A mass function can thus be seen as:
 - ▶ a generalized set
 - ▶ a generalized probability distribution

Representation of information

Other representations — Belief and Plausibility Functions

- ▶ A MF m is in **one-to-one correspondence** (each function represents the same information) with :
 - ▶ a **belief function** Bel defined for all $A \subseteq \Omega$ by:

$$Bel(A) = \sum_{\emptyset \neq B \subseteq A} m(B),$$

$Bel(A)$ represents the total degree of belief supporting the fact that $\omega_0 \in A$ (**Total support in A**)

- ▶ a **plausibility function** Pl defined for all $A \subseteq \Omega$ by:

$$Pl(A) = \sum_{A \cap B \neq \emptyset} m(B) = Bel(\Omega) - Bel(\bar{A})$$

with $\bar{A} = \Omega \setminus A$.

$Pl(A)$ represents the total sum of beliefs that are not in contradiction with A (**Consistency with A**)

Representation of information

Example

With $\Omega = \{a, b, c\}$, $m(\{a\}) = 0.3$, $m(\{b\}) = 0.4$ and $m(\Omega) = 0.3$

Let us compute $Bel(\{a, b\})$ as an example, we have

$$\begin{aligned} Bel(\{a, b\}) &= \sum_{B: \emptyset \neq B \subseteq \{a, b\}} m(B) \\ &= m(\{a\}) + m(\{b\}) + m(\{a, b\}) = .7 \end{aligned}$$

For Pl , let us compute $Pl(\{a, b\})$ as an example as well

$$\begin{aligned} Pl(\{a, b\}) &= \sum_{B: B \cap \{a, b\} \neq \emptyset} m(B) \\ &= m(\{a\}) + m(\{b\}) + m(\{a, b\}) + m(\{a, c\}) + m(\{b, c\}) + m(\Omega) \\ &= 1 \end{aligned}$$

Representation of information

Example

With $\Omega = \{a, b, c\}$, $m(\{a\}) = 0.3$, $m(\{b\}) = 0.4$ and $m(\Omega) = 0.3$

<i>bin.order</i>		<i>m</i>	<i>Bel</i>	<i>Pl</i>
000	\emptyset			
001	<i>a</i>	.3		
010	<i>b</i>	.4		
011	<i>a, b</i>			
100	<i>c</i>			
101	<i>a, c</i>			
110	<i>b, c</i>			
111	<i>a, b, c</i>	.3		

Representation of information

Example in R with the `ibelief` package

```
> library(ibelief)
> m=c(0,.3,.4,0,0,0,0,.3)
> pl=mtopl(m)
> bel=mtobel(m)
```

Representation of information

Example

Example: With $\Omega = \{a, b, c\}$, $m(\{a\}) = 0.3$, $m(\{b\}) = 0.4$ and $m(\Omega) = 0.3$

<i>bin.order</i>		<i>m</i>	<i>Bel</i>	<i>PI</i>
000	\emptyset			
001	<i>a</i>	.3	.3	.6
010	<i>b</i>	.4	.4	.7
011	<i>a, b</i>		.7	1
100	<i>c</i>			.3
101	<i>a, c</i>		.3	.6
110	<i>b, c</i>		.4	.7
111	<i>a, b, c</i>	.3	1	1

Representation of information

Properties

- ▶ $Bel(\emptyset) = Pl(\emptyset) = 0$
- ▶ $Bel(\Omega) \leq 1$ and $Pl(\Omega) \leq 1$ (as $m(\emptyset)$ could be positive)
- ▶ $Bel(A) \leq Pl(A)$
- ▶ $Pl(A) = 1 - Bel(\bar{A})$
- ▶ If m is Bayesian (i.e. all focal elements are singletons) then $Bel = Pl$ is a **probability measure**

Representation of information

Intervals $[Bel(A), Pl(A)]$

- ▶ The **uncertainty** about a proposition A is represented by two numbers: $Bel(A)$ and $Pl(A)$, with $Bel(A) \leq Pl(A)$.
- ▶ The intervals $[Bel(A), Pl(A)]$ have **maximum length** when m is **vacuous** ($m = m_\Omega$).
 - ▶ In this case: $Bel(A) = 0$ for all $A \neq \Omega$ and $Pl(A) = 1$ for all $A \neq \emptyset$
- ▶ The intervals $[Bel(A), Pl(A)]$ have **minimum length** when m is **Bayesian**.
 - ▶ In this case, for all A :

$$Bel(A) = Pl(A) = \sum_{\omega \in A} m(\omega)$$

and Bel and Pl are probability measures.

Representation of information

Consonant mass function

- ▶ If m has its **focal elements nested** ($A_1 \subset A_2 \subset \dots \subset A_n$, with A_i , $i \in \{1, 2, \dots, n\}$ the focal elements of m), m is said to be **consonant**.
- ▶ In this case, for all $A \subseteq \Omega$, $B \subseteq \Omega$:

$$Bel(A \cap B) = \min(Bel(A), Bel(B))$$

and

$$Pl(A \cup B) = \max(Pl(A), Pl(B))$$

meaning Pl is a **possibility measure** and Bel is its dual **necessity measure**.

Representation of information

Combining information

Decision making

Conclusion

Conjunctive Rule of Combination

- ▶ Two mass functions m_1 and m_2 from two **reliable and distinct sources** of information can be combined using the **conjunctive rule of combination (CRC)** defined by:

$$(m_1 \odot m_2)(A) = m_1 \odot_2(A) = \sum_{B \cap C = A} m_1(B) \cdot m_2(C), \quad \forall A \subseteq \Omega.$$

Cunjunctive Rule of Combination

Example

With $\Omega = \{a, b, c\}$, let us consider a MF m_1 and another independent MF m_2 s.t.

$$\begin{cases} m_1(\{b\}) & = .4 \\ m_1(\{a, b\}) & = .6 \end{cases} \quad \text{and} \quad \begin{cases} m_2(\{b, c\}) & = .3 \\ m_2(\{a, b, c\}) & = .7 \end{cases}$$

CRC	$m_2(\{b, c\}) = .3$	$m_2(\{a, b, c\}) = .7$
$m_1(\{b\}) = .4$	$\{b\} \cap \{b, c\} = \{b\}$ $.4 \times .3 = .12$	$\{b\} \cap \{a, b, c\} = \{b\}$ $.4 \times .7 = .28$
$m_1(\{a, b\}) = .6$	$\{a, b\} \odot \{b, c\} = \{b\}$ $.6 \times .3 = .18$	$\{a, b\} \odot \{a, b, c\} = \{a, b\}$ $.6 \times .7 = .42$

The CRC $m = m_1 \odot m_2$ is given by

- ▶ $m(\{b\}) = .4 \times .3 + .4 \times .7 + .6 \times .3 = .58$
- ▶ $m(\{a, b\}) = .6 \times .7 = .42$

- ▶ **If and only if** m_1 and m_2 are two **reliable** and **distinct** mass functions (Axiomatic justifications, see e.g. Smets 2007)
- ▶ **Dempster's rule := CRC normalized**: $m_{1\oplus 2}(\emptyset) = 0$ and

$$(m_1 \oplus m_2)(A) = m_{1\oplus 2}(A) = \frac{1}{1 - \kappa} \sum_{B \cap C = A} m_1(B) \cdot m_2(C), \quad \forall A \neq \emptyset$$

with $\kappa = \sum_{B \cap C = \emptyset} m_1(B) \cdot m_2(C)$ (called **degree of conflict**).

Disjunctive Rule of Combination

- ▶ If the sources are **distinct but only one of the sources is reliable** (and we don't know which one), the **disjunctive rule of combination (DRC)** defined as follows can be applied:

$$(m_1 \oplus m_2)(A) = m_1 \oplus_2(A) = \sum_{B \cup C = A} m_1(B) \cdot m_2(C), \quad \forall A \subseteq \Omega.$$

Properties for these rules

- ▶ With these rules \odot , \oplus and \cup , the order the sources are combined does not change the results
- ▶ $m_1 \odot m_2 = m_2 \odot m_1$ (**Commutativity**) (Likewise for \oplus and \cup)
- ▶ $(m_1 \odot m_2) \odot m_3 = m_1 \odot (m_2 \odot m_3)$ (**Associativity**) (Likewise for \oplus and \cup)

Combining information

Example

	m_1	m_2	$m_1 \odot m_2$	$m_1 \oplus m_2$	$m_1 \ominus m_2$
\emptyset					
a	.3				
b	.4				
a, b		.5			
c					
a, c		.1			
b, c					
a, b, c	.3	.4			

Combining information

Example in R with the ibelief package

```
> m1=c(0,.3,.4,0,0,0,0,.3)
```

```
> m2=c(0,0,0,.5,0,.1,0,.4)
```

```
> mcunjunctive = DST(cbind(m1,m2),1)
```

```
> mdempster = DST(cbind(m1,m2),2)
```

```
> mdisjunctive = DST(cbind(m1,m2),4)
```

Combining information

Example

	m_1	m_2	$m_1 \odot m_2$	$m_1 \oplus m_2$	$m_1 \ominus m_2$
\emptyset			.04		
a	.3		.30	.312	
b	.4		.36	.375	
a, b		.5	.15	.156	.35
c					
a, c		.1	.03	.031	.03
b, c					
a, b, c	.3	.4	.12	.125	.62

Misconception about Dempster's rule

- ▶ Following an old report from Zadeh (1979) - it is still nowadays repeated that “Dempster's rule yields counterintuitive results” (usually used as a justification to introduce new combination rules)
- ▶ Zadeh's example: $\Omega = \{a, b, c\}$, two experts reporting:
 - ▶ Expert 1: $m_1(\{a\}) = 0.99$, $m_1(\{b\}) = 0.01$ and $m_1(\{c\}) = 0$
 - ▶ Expert 2: $m_2(\{a\}) = 0$, $m_2(\{b\}) = 0.01$ and $m_2(\{c\}) = 0.99$
- ▶ Then $m_1 \oplus_2(b) = 1$, which is claimed to be “counterintuitive” by some authors because both experts considered b as very unlikely.
- ▶ But:
 - ▶ Both experts are totally reliable.
 - ▶ Expert 1 indicates that c is absolutely impossible.
 - ▶ Expert 2 indicates that a is absolutely impossible.
- ▶ Then b is the only possibility. We are in a situation, which is possible for both experts, where the true answer is b .
- ▶ Dempster's rule does produce sound results when used in accordance with the axioms, from which it derived.

Discounting

A simple correction example (Shafer, 1976).

Discounting of a mass function (MF) m is defined by (Shafer, 1976):

$$\begin{cases} {}^\alpha m(A) &= (1 - \alpha)m(A), \quad \forall A \subset \Omega, \\ {}^\alpha m(\Omega) &= (1 - \alpha)m(\Omega) + \alpha, \end{cases}$$

where $\alpha \in [0, 1]$ is the **discount rate**.

Discounting

A simple correction example (Shafer, 1976).

Discounting of a mass function (MF) m is defined by (Shafer, 1976):

$$\begin{cases} \alpha m(A) &= (1 - \alpha)m(A), \quad \forall A \subset \Omega, \\ \alpha m(\Omega) &= (1 - \alpha)m(\Omega) + \alpha, \end{cases}$$

where $\alpha \in [0, 1]$ is the **discount rate**.

Example:

- ▶ $\Omega = \{a, b, c\}$
- ▶ $m(\{a\}) = .2$, $m(\{b\}) = .4$ and $m(\{a, b\}) = .4$
- ▶ With discount rate $\alpha = .2$:

$$\begin{cases} \alpha m(\{a\}) &= .8 \times .2 &= .16 \\ \alpha m(\{b\}) &= .8 \times .4 &= .32 \\ \alpha m(\{a, b\}) &= .8 \times .4 &= .32 \\ \alpha m(\Omega) &= .8 \times .0 + .2 &= .20 \end{cases}$$

Discounting

Example in R with the ibelief package

```
> m=c(0,.2,.4,.4,0,0,0,0)
```

```
> mdisc = discounting(m,.8)
```

L'argument placé dans cette fonction est $1 - \alpha = .8$ qui est le degré de fiabilité de la source (80% des masses sont gardées dans ce cas)

Discounting

Results in terms of masses transfers

For each focal element B of m_S :

- ▶ A part $(1 - \alpha) \cdot m_S(B)$ remains on B .
- ▶ A part $\alpha \cdot m_S(B)$ is transferred to Ω .

Discounting

Matrix representation (Smets, 2002)

Discounting ${}^\alpha m$ is a **generalization** of m (${}^\alpha m \supseteq_s m$):

$${}^\alpha m(A) = \sum_{B \subseteq \Omega} {}^\alpha G(A, B) m(B),$$

with ${}^\alpha \mathbf{G}$ a **generalisation matrix** defined by:

$${}^\alpha G(A, B) = \begin{cases} 1 - \alpha & \text{if } A = B \neq \Omega, \\ \alpha & \text{if } A = \Omega \text{ and } B \subset A, \\ 1 & \text{if } A = B = \Omega \\ 0 & \text{otherwise.} \end{cases}$$

$${}^\alpha \mathbf{G} = \begin{pmatrix} 1 - \alpha & 0 & \dots & 0 & 0 \\ 0 & 1 - \alpha & \dots & 0 & 0 \\ 0 & 0 & \ddots & 0 & 0 \\ 0 & 0 & \dots & 1 - \alpha & 0 \\ \alpha & \alpha & \dots & \alpha & 1 \end{pmatrix}$$

Discounting

Matrix representation: example

With $\alpha = .2$, $\beta = 1 - \alpha = .8$ and $\Omega = \{a, b, c\}$:

$$\begin{array}{l} 000 : \emptyset \\ 001 : \{a\} \\ 010 : \{b\} \\ 011 : \{a, b\} \\ 100 : \{c\} \\ 101 : \{a, c\} \\ 110 : \{b, c\} \\ 111 : \{a, b, c\} \end{array} \begin{pmatrix} .0 \\ .16 \\ .32 \\ .32 \\ .0 \\ .0 \\ .0 \\ .20 \end{pmatrix} = \begin{pmatrix} \beta & & & & & & & & \\ & \beta & & & & & & & \\ & & \beta & & & & & & \\ & & & \beta & & & & & \\ & & & & \beta & & & & \\ & & & & & \beta & & & \\ & & & & & & \beta & & \\ \alpha & \alpha & \alpha & \alpha & \alpha & \alpha & \alpha & \alpha & 1 \end{pmatrix} \cdot \begin{pmatrix} .0 \\ .2 \\ .4 \\ .4 \\ .0 \\ .0 \\ .0 \\ .0 \end{pmatrix}$$

Representation of information

Combining information

Decision making

Conclusion

Decision making

Making Hard Decisions

- ▶ A way to make a **hard decision** is to choose a decision $d = \omega \in \Omega$ maximizing a probability transform of m , as for example using the Pignistic transform $BetP$ defined by:

$$BetP(\{\omega\}) = \sum_{A \subseteq \Omega, \omega \in A} \frac{m(A)}{|A| (1 - m(\emptyset))}, \quad \forall \omega \in \Omega .$$

- ▶ Example: With $\Omega = \{a, b, c\}$, $m(\{a\}) = 0.3$, $m(\{b\}) = 0.4$ and $m(\Omega) = 0.3$

$$BetP = \begin{cases} \{a\} \mapsto 0.3 + \frac{0.3}{3} = 0.4 \\ \{b\} \mapsto 0.4 + \frac{0.3}{3} = 0.5 \\ \{c\} \mapsto 0.0 + \frac{0.3}{3} = 0.1 \end{cases}$$

Decision making

Making Hard Decisions: Example in R with the ibelief package

```
> m=c(0,.3,.4,0,0,0,0,.3)
```

```
> betp = mtobetp(m)
```

- ▶ A way to make a **partial decision** is to choose a set-valued decision $d = A \subseteq \Omega$ composed of elements of Ω , which are **not dominated according to a preference relation**:

1. The relation of **strong dominance or interval dominance** defined by

$$\omega \succeq_{sd} \omega' \iff Bel(\{\omega\}) \geq PI(\{\omega'\})$$

2. The relation of **weak dominance** defined by

$$\omega \succeq_{wd} \omega' \iff Bel(\{\omega\}) \geq Bel(\{\omega'\}) \text{ and } PI(\{\omega\}) \geq PI(\{\omega'\})$$

Decision making

An example with partial decisions using the strong and weak dominance criteria

Example: With $\Omega = \{a, b, c\}$, $m(\{a\}) = 0.3$, $m(\{b\}) = 0.4$ and $m(\Omega) = 0.3$

$$Bel = \begin{cases} \{a\} \mapsto 0.3 \\ \{b\} \mapsto 0.4 \\ \{c\} \mapsto 0.0 \end{cases} \quad Pl = \begin{cases} \{a\} \mapsto 0.6 \\ \{b\} \mapsto 0.7 \\ \{c\} \mapsto 0.3 \end{cases}$$

Relation SD	Non-dominated
$Bel(\{b\}) = .4 \not\geq Pl(\{a\}) = .6$ and $Bel(\{c\}) = 0 \not\geq Pl(\{a\}) = .6$	a
$Bel(\{a\}) = .3 \not\geq Pl(\{b\}) = .7$ and $Bel(\{c\}) = 0 \not\geq Pl(\{b\}) = .7$	b
$Bel(\{a\}) = .3 \geq Pl(\{c\}) = .3$ (so $a \succeq_{sd} c$)	-

Conclusion using SD: $d = \{a, b\}$.

Relation WD	Dominated
$Bel(\{b\}) = 0.4 \geq Bel(\{a\}) = 0.3$ and $Pl(\{b\}) = 0.7 \geq Pl(\{a\}) = 0.6$ (so $b \succeq_{wd} a$)	a
$Bel(\{b\}) = 0.4 \geq Bel(\{c\}) = 0.0$ and $Pl(\{b\}) = 0.7 \geq Pl(\{c\}) = 0.3$ (so $b \succeq_{wd} c$)	c

Conclusion using WD: $d = \{b\}$.

Representation of information

Combining information

Decision making

Conclusion

- ▶ Dempster-Shafer (DS) theory of belief functions is a **flexible mathematical framework** for dealing with **imperfect information**.
- ▶ It encompasses **probability theory** and **set-membership** approaches as special cases.
- ▶ Belief functions can be seen as weighted opinions.
